Field of the Invention The present invention relates generally to methods and systems for making aggregate distribution maps, and specifically to methods and systems for making fee distribution maps. 2. Related Art Recently, there has been an explosive growth in the number of over-the-top (OTT) and multi-platform (MP) video, i.e., linear, and non-linear media streaming applications. Some applications are primarily directed to video streaming, while others provide video with additional services such as remote camera access, online gaming or interactive real time e-learning. These applications may rely on network-based video content access,

over-the-top video services accessed via a broadband provider, and online video services. The nature of the network-based video content access are substantially different from the nature of the over-the-top and online services. Specifically, the distribution model of over-the-top video services is substantially different from the model of the online video services due to different market dynamics. OTT video services are generally provided by a content provider to an end user over a network such as the Internet. In this model, a user receives a video stream, which includes, typically, a plurality of segments (e.g., 15-45 second clips), and usually each segment is responsible for playing once per second for the entire duration of the video stream. A user may also be able to pause the video, but in general, the video stream may only be paused for a user to consume additional content. In contrast to the OTT video services, online video services do not provide users with on

demand video content streaming, but usually provide only a relatively small portion of a larger online video content, such as the first few minutes of a seven minute video clip.

Typically, the online video services deliver the video content to the user on a random basis and/or may interrupt the delivery of the video content at any time, for example, to promote a new online video content, an upcoming online event, a promotion, etc. Different content providers may provide OTT and online video services 648931e174

The download links, provided below, are direct connections to the .The present invention relates to a liquid dispenser for inkjet printers and, more particularly, to a continuous inkjet printhead having a variable nozzle plate that regulates the flow of ink from nozzles to the surrounding environment. Jet printers deposit ink on media, such as paper, by means of a printhead. These printheads are typically comprised of an array of nozzles, from which tiny drops of ink are ejected. The distance

between these nozzles and the media, upon which the ink is to be deposited, is known as the printhead's print zone. The printhead typically includes a metal base with an array of nozzles formed in the metal base surface. A polymeric layer is placed on top of the base. Liquid ink is then deposited on the polymeric layer and is channeled from a reservoir in the printhead to the nozzles by an array of channels formed in the polymeric layer. The nozzles are typically fabricated with a ceramic such as silicon carbide. These nozzles are often formed with a dog-boning technique. First, the ceramic is etched to form a nozzle plate that comprises an array of nozzle holes on a first side. A thin membrane is then formed on the first side of the nozzle plate. A second side of the nozzle plate is then ground to remove the membrane and the nozzle plate is finished to form a nozzle aperture on the first side of the nozzle plate. This process forms the

dog-boning nozzles with a length of 4-4.5 cm. However, these nozzles produce droplets that have a mean diameter of greater than 5 cm. While the nozzles are effective at controlling the size of the droplets, this size of droplet is too large for a high quality print. Thus, the print quality is limited with these nozzles. A continuous inkjet printhead may be used to improve the quality of a print. In a continuous inkjet printer, ink is directed through a continuous jetting path to the printhead. The continuous jetting path includes multiple nozzles that can be continuously turned on and off
